Original Research Article

ABSTRACT

The innovative method to assess the true genetic potentialities of inbreds was an effective way to identify potential inbreds. The pooled analysis methods viz., simple pooled gca method, per cent pooled gca method and weighted pooled gca method was used to calculate overall combining ability. In the present study, two heterotic populations were crossed in the line x tester method. These innovative methods were used to assess overall combining ability based on pooled analysis using eight different economic traits in baby corn. In Population A, the inbreds viz., P48, P41, P30, P14 and P50 were considered as top five for yield-related traits. Likewise, the inbreds viz., H95, H81, H51, H20 and H97 belonging to Population B were best combiners for yield and its related traits.

Keywords: Combing ability; simple pooled gca method; per cent pooled gca method; weighted pooled gca method.

1. INTRODUCTION

Maize being a versatile crop and “Queen of cereal”, cultivated globally for its various potential uses. Maize has diverse utilization patterns as both food and fodder all over the world. Corn like Popcorn, Pod corn, Sweet corn and Baby corn are different types of corns with distinguished uses [1]. Baby corn (*Zea mays*) refers to whole, entirely edible cobs of immature corn harvested just before fertilization at the silk emergence stage. [2]. It is a highly nutritious vegetable having on par or higher quality of nutrition compared to seasonal vegetables. It is one of the richest sources of phosphorus, along with proteins, vitamins and iron. Due to its more tremendous potentiality for both internal and export value with year-round income, it is now widely accepted among producers and consumers [3-6].

It is cultivated in tropics, subtropics and temperate regions from sea level to more than 4000m above sea level. In India, it is developed in an area of 9.18 m. ha with the production of about 27.23 m. t and 2965 kg ha⁻¹ productivity. In Karnataka, it is cultivated on an area of 2.23 m. ha with the production of about 3.73 m. t and 2777 kg ha⁻¹ productivity [7].

Combining ability analysis is the most powerful tool in identifying the best combiners that may be used in crosses either to exploit heterosis or to accumulate productive genes [8,9]. It also helps to understand the genetic architecture of various characters that enable the breeder to design effective breeding plans for another improvement of existing breeding material. Information on heterotic patterns and combining abilities among maize germplasm is essential in maximizing the effectiveness of hybrid development [10-12].

Nevertheless, baby corn has been gaining importance from the last few decades, there is a

lack of widespread and superior hybrids and inbreds developed which are highly profitable to farmers and very much fewer population improvement programmes has been initiated in India. Considering above facts, the present investigation was carried out for the improvement of two populations [(PDM 4441 X PDM 53) and (HKI 1105 X HKI 323)] using the line × tester method during Kharif, 2018 to Rabi, 2020.

2. MATERIALS AND METHODS

Twenty-six F₄ inbreds of Population A (PDM 4441 x PDM 53) were crossed with two reciprocal testers (HKI 1105 and HKI 323) and one standard tester (PDM 260-1) a line × tester mating design to derive 78 single cross-test hybrids. Similarly, twenty-six F₄ inbreds of Population B (HKI 1105 x HKI 323) were crossed with two reciprocal testers (PDM 4441 and PDM 53) and one standard tester (PDM 260-1) in line × tester mating design to derive 78 single cross-test hybrids. These hybrids along with parents and checks, were evaluated in randomized block design with two replications during Rabi 2020 at Botanygarden, Department of Genetics and Plant Breeding, University of Agricultural Sciences, Dharwad (Karnataka), India. The experimental plot was laid out with 3 m length with 60 × 20 cm spacing. At the time of primary flowering, detasselling was carried out in hybrids, and baby corns were harvested preferably 1-3 days of silk emergence depending on the growing season [2]. The materials used to generate single cross hybrids are presented in Table 1.

The observations were recorded on ten randomly selected plants for quantitative characters viz., days to 50% silking, husked cob weight (g), dehusked cob weight (g), cob length (cm), cob diameter (cm), number of cob per plant and green fodder yield per plant (g). The hybrids were estimated for combining ability effects and their variances [13].

3. RESULTS AND DISCUSSION

3.1 General Combining Ability (GCA) Effects

Selection of parents is a prerequisite for the success of any breeding programme. The combining ability analysis reveals the gca and sca effects along with the gene action of the characters [14]. The gca effects for baby corn yield-related traits were presented and discussed below.

3.1.1 Baby corn yield per plant without husk (g)

Twelve newly developed F₄ inbred lines (Population A) expressed significant positive gca effects for the above trait. The top three lines viz., P27 (8.99), P36 (8.48) and P17 (7.48) displayed the highest significant gca effects in the desirable direction. Among the three testers, HKI 323 showed substantial positive gca effects

(3.37) (Table 2). With respect to Population B, ten new F₄ lines showed positive significant gca effects for the trait. The lines *namely* H94 (13.30) H99 (12.02) and H61 (6.15) occupied top three positions. Among three testers, PDM 4441 (3.13) recorded significant positive gca effects (Table 3).

3.1.2 Baby corn yield per plant with husk (g)

While considering Population A, fourteen lines registered positive gca effects and the lines P36 (34.77), P11 (26.29) and P27 (24.27) were highly significant. Among testers, HKI 323 (16.09) recorded substantial positive gca effects (Table 2). In Population B, eleven lines were in a desirable positive direction. New F₄ Lines *viz.*, H94 (54.71), H99 (40.25), and H8 (28.96) revealed highly significant gca effects in positive direction. Among three testers, PDM 4441 (16.00), PDM 53 (4.07) documented significant positive effects (Table 3).

3.1.3 Days to 50% silking

In line with the trait, days to 50% silking, three inbred lines out of 26 new F_4 lines manifested significant gca effects, among which lines P10 and P11 (-0.35) registered maximum gca effects in the desirable negative direction. Among the PDM 260-1 (0.11) recorded a significant gca effect (Table 2).

In Population B, nine F_4 lines showed significance in the negative direction. The lines viz., H 91 (-2.22), H41 (-2.39) reported highly significant gca effects in the desirable negative direction. Among three testers, PDM 53 (-0.80) and PDM 4441 (-0.75) recorded significant negative gca effects (Table 3).

3.1.4 Number of ears per plant

Among the 26 new F_4 lines derived from Population A, gca effects were significant in the desired direction in two lines. The lines P36 (0.39), P17 (0.53) occupied the top two positions concerning the number of ears per plant. There were no significant positive gca effects among the testers (Table 2).

With respect to gca effects of derived F_4 lines involved in Population B, lines viz., H99 (0.51) and H59 (-0.42) obtained positive and negatively significant gca effects respectively (Table 3). None of the testers under study displayed significant gca effects in desirable direction.

3.2 Specific Combining Ability (sca Effects)

Specific combining ability can be defined as ability of a hybrid combination to perform better or poorer than expected based on the average performance of inbred parental lines [15]. The sca effects of 78 Single crosses derived from 26 lines and 3 testers were estimated and described below for important baby corn traits viz., baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), days to 50 % silking and number of cobs per plant in both the Population A and B.

3.2.1 Baby corn yield per plant without husk (g)

Considering Population A, 31 crosses showed significant positive sca effects for the above studied trait. The cross P12 × HKI 1105 (11.09) expressed the highest sca effects and P11 ×

PDM 260-1 (-11.22) showed the lowest sca effects. The top three best combiners that registered maximum positive sca effects were P12 × HKI 1105 (11.09), P47 × HKI 323 (10.40), P27 × HKI 323 (10.29) (Table 4).

With respect to sca effects of Population B, three single crosses registered significant sca effects in the desirable direction. The crosses namely, H61 × PDM 53 (21.66), H5 × PDM 260-1 (11.00) and H 49 × PDM 53 (10.28) were occurred to be top three cross combinations (Table 5).

3.2.2 Baby corn yield per plant with husk (g)

The top three crosses with maximum sca effects in desirable direction were P47 × HKI 323 (53.83), P12 × HKI 1105 (39.45), P11 × HKI 1105 (37.31). Maximum significantly positive sca effects in desirable direction was exhibited by cross P47 × HKI 323 (53.83) for the trait, whereas minimum negative sca effects was shown by hybrid P32 × HKI 323 (-47.52) in case of Population A (Table 4).

Regarding sca effects of Population B, the three best crosses that catalogued maximum positive sca effects were H 5 × PDM 260-1 (73.58), H20 × PDM 4441 (51.06) and H61 × PDM 53 (49.34) (Table 5).

3.2.3 Days to 50% Silking

A total of sixteen derived hybrids of Population A showed significant sca effects in negative direction. Among them, maximum significant sca effects in desirable direction was observed in crosses viz., P39 × HKI 1105 (-5.80) and P13 × HKI 323 (-2.92) (Table 4).

3.2.4 Number of ears per plant

With respect to derived hybrids in Population A, three crosses viz., P47 × HKI 323, P40 × HKI 323 and P19 × HKI 323 involving tester HKI 323 exhibited positive significant sca effects values of (0.80) (0.66) and (0.56) respectively. The largest positive sca effects were recorded by cross P47 × HKI 323 (0.80) (Table 4).

The top three combiners that registered positive sca effects were H16 × PDM 53 (0.84), H 61 × PDM 53 (0.56) and H22 × PDM 260-1 (0.44) (Table 5).

3.3 Innovative Methods for Assessment of Pooled GCA Effects

The three innovative and effective methods to calculate pooled gca scores based on combining ability of inbred lines were as follows.

3.3.1 Simple pooled gca effects

In this method, significant gca effect in desirable direction is given score of + 1 and -1 score to gca effects significant in undesirable direction (Arunachalam and Bandyopadhyay, 1979). These values are added over different yield attributing traits to arrive at pooled score of gca effects.

In Population A test F₄ lines, based on simple pooled gca score method, the inbred lines *viz.*, P34, P27 and P36 are recognized as most potential general combiners, and among the testers, HKI 323 was emerged as best combiner for various quantitative traits of baby corn *viz.*, baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking, baby corn weight without husk (g), baby corn weight with husk (g), baby corn length (cm) and baby corn diameter (cm) (Table 6).

The F₄ lines of Population B *viz.*, H94, H8, H99, H61 and H6 and among testers, PDM 4441 was found to be good general combiner for the traits *namely* baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking, baby corn weight without husk (g), baby corn weight with husk (g), baby corn length (cm) and baby corn diameter (cm) (Table 7).

3.3.2 Per cent pooled gca effects

It is considerate to calculate pooled scores of gca by ensuring quantification of differences in gca effects among parental genotypes by utilizing the actual gca values. (Deshpande, 2005). In per cent gca method, gca effects of parents for each character is converted into per cent values by comparing with respective F₁ means. Then individual per cent gca values are pooled to get pooled gca score.

With respect to per cent pooled gca method also the F₄ inbred lines (Population A) *viz.*, P 27, P 36 and P 17 were occupied top three for the traits (Table 8) *viz.*, baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking,

baby corn yield without husk (g), baby corn yield with husk (g), baby corn length (cm) and baby corn diameter (cm).

Likewise, in case of Population B, the F₄ lines *viz.*, H94, H99 and H6 were registered as best combiners in per cent pooled gca method (Table 9) for the traits *viz.*, baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking, baby corn yield without husk (g), baby corn yield with husk (g), baby corn length (cm) and baby corn diameter (cm).

3.3.3 Weighted pooled gca effects

In this method, each trait was given a certain weightage based on the important of trait in the crop and these ascertained values were further multiplied with the respective per cent gca values, worked out for each trait and then added to obtain pooled gca score for each parent.

However, in general, the weighted gca method was found to be more relevant and effective in differentiating the inbred lines in Population A and Population B compared to the earlier two methods.

In weighted pooled gca method, the F₄ inbred lines (Population A) *viz.*, P 48, P 41, P30 and P 14 were regarded as best combiners for the traits (Table 10) *viz.*, baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking, baby corn yield without husk (g), baby corn yield with husk (g), baby corn length (cm) and baby corn diameter (cm).

Likewise, in the case of Population B, the F₄ lines *viz.*, H81 H95 and H 51 were registered as best combiners in weighted pooled gca method (Table 11) for the traits *viz.*, baby corn yield per plant without husk (g), baby corn yield per plant with husk (g), number of ears per plant, days to 50 % silking, baby corn yield without husk (g), baby corn yield with husk (g), baby corn length (cm) and baby corn diameter (cm).

4. CONCLUSION

The genetic diversity existing between breeding populations and diverse populations lay the foundation for success of any plant breeding programmes, which determines the magnitude and nature of variability created for combining ability (Hallauer, 1984). In case of simple pooled gca method, P34, P27 and P36 (Population A)

were occupied top three positions and whereas in case of Population B, H94, H99 and H61 were found as best combiners for important baby corn traits.

While based on pooled weighted gca method in Population A, P48, P41 and P14 were found as best and outperforming inbred line compared to the rest for all the baby corn traits, and with respect to Population B, H81 and H57 were found to be best-inbred lines for baby corn traits.

Hence based on the weighted pooled gca method, the inbred lines found to be potential for baby corn traits can be further used as parents in baby corn breeding corresponding to the development of superior baby corn hybrids. These above mentioned new promising inbred also gain considerable importance to develop new populations through subsequent successive cycles of reciprocal recurrent selection in population improvement programs of baby corn breeding.
